Regulation of *Eurotium repens* Reproduction and Secondary Metabolite Production

M. AbdEl-Mongy  
*Microbial Biotechnology Department, Genetic Engineering and Biotechnology Research Institute, Minoufiya University, Sadat City, Egypt.*

*Eurotium* species often dominate the fungal population in stored grain and are responsible for spoilage of jams, dried foods, dried salted fish and sponge cake (Abellana *et al.*, 1999 and Bluham *et al.*, 2005). *Eurotium repens* sexually reproduces as an ascomycete (telomorph) whereas asexual conidial reproduction of the same fungus (Anamorph) is classified as *Aspergillus repens*.

Water activity (a$_w$) measurements estimate the proportion of the available water in a system, *i.e.* the water available for biological (biochemical) and chemical reaction. Water activity can be controlled through water removal or solute addition; solutes that can be used for this purpose are polyols, salts and sugars (Rose, 1983). Xerophilic fungi are characterized as being capable of growing below a$_w$ of 0.85, and are most commonly associated with intermediate moisture foods, including cereals, nuts species and several dried food stuffs (Hocking, 1988). The majority of xerotolerant fungi belongs to the genera *Aspergillus* and *Penicillium* are perfect forms of *Aspergillus* such as *Eurotium* and *Emericella*. One of the principal factors controlling the growth of these organisms in food is a$_w$; the effective growth range can be as low as 0.61 (Corry, 1987 and Jay, 1992).

**Keywords:** *Aspergillus repens* reproduction in fungi, Amino acids, Sucrose.
Low $a_w$ significantly reduced spores germination of *Aspergillus* spp. (Nesci *et al.*, 2003 and Ni & Streett, 2005). The spores only germinated on a medium with high $a_w$ values; 0.982 and 0.937, while the spores did not germinate with $a_w$ values 0.747 and 0.809.

Fungi reproduce asexually under favorable condition and sexually under stress conditions (Griffin, 1994). Bluhm *et al.* (2005) reported that *Aspergillus nidulans* and *Aspergillus flavus* strains grew only at 0.98 $a_w$. At 0.86 $a_w$ No growth of *Aspergillus nidulans* or *Aspergillus flavus* was visible after 8 days. At 0.83 $a_w$, *Aspergillus nidulans* was not observed, nor were sclerotia produced by *Aspergillus flavus*.

Secondary metabolites are low-molecular-weight natural products generated by filamentous fungi, plants, algae, bacteria, and animals in response to environmental abiotic and biotic stimuli. Secondary metabolites have a strong impact on humankind via their application in health, medicine, agriculture, and industry; they include useful (e.g. antibiotics) and detrimental compounds (e.g. mycotoxins). These metabolites are frequently associated with asexual and sexual development (Chang *et al.*, 2001 and Wilkinson, *et al.*, 2004). Adams *et al.* (1998) and Pena *et al.* (1998) found a positive correlation between cleistothecial formation and secondary metabolite production in wild type and mutant strains of *Emericella nidulans*.

*Aspergillus* spp. produce an array of secondary metabolites including aflatoxin, cyclopiazonic acid, aflatrem, patulin, penicillin, kojic acid, lovastatin, carotenoids, and spore pigments; novel secondary metabolites have also been discovered that they are synthesized from so called silent gene clusters in *A. nidulans*, such as terrequinone A, monodictyphenone, emodins, and polyketides (Bok *et al.*, 2009).

Some ascomycetes may require exogenous vitamins, minerals, or other natural materials for ascocarp production that are often not duplicated in synthetic media (Moore – Landecker, 1992). *Venturia inaequalis* produced large number of ascocarps with glycine but no ascocarps were produced with ammonium tartrate (Ross & Brenner, 1971). Engelkes *et al.* (1997) found that the tyrosine was one of the better nitrogen sources for production of *Taloromyces flavus* ascospores. Also, fatty acids or related lipids are important for sexual development of filamentous fungi (Nukina *et al.*, 1981 and Goodrich – Tanrikulu *et al.*, 1998).

The objectives of this study were to assess the metabolic regulation through stress conditions on growth, reproduction and secondary metabolites biosynthesis of *Eurotium repens* which cause spoilage of fruits.

**Materials and Methods**

*Fungal strain*

The fungal isolate was isolated from spoiled fruit and identified as *Eurotium repens* according to Rapper & Fennel (1965).
Media

Dox's agar medium (sucrose, 20 g; NaNO₃, 2g; KH₂PO₄, 1g; KCl, 0.5 g; MgSO₄·7H₂O, 0.5 g; Fe SO₄·7H₂O, 0.001 g; agar 20 g and distilled water, 1L) and Malt extract agar medium (malt extract, 20 g; peptone, 1 g; dextrose, 20g; agar, 20 g and distilled water, 1L) were used for isolation, cultivation and identification of the fungal isolate.

Growth and culture conditions

Dox's agar medium was supplemented with different sucrose concentrations; 2, 30, 40, 50, 60, 70 and 80% (w/v) to adjust the water activity (aw) 0.99, 0.86, 0.82, 0.79, 0.75, 0.72 and 0.70, respectively according to Hefnawy (1993). A plug of inoculum from the leading edge of a colony growing on an agar plate was either inoculated in the center of another plate containing the above medium (for growth and detection of the anamorph and teleomorph stages) or transferred to 500 ml conical flask(s) for detection of amino acids, secondary metabolites, metals and antimicrobial activity.

Dox's agar medium supplemented with different sucrose concentrations and pHs, were inoculated and incubated were adjusted at different temperatures for 8 days to study their effects on anamorph and teleomorph stages formation.

Nitrogen free Dox's agar medium supplemented with different sucrose concentrations was amended with selected amino acids in equivalent weigh to N of NaNO₃ and certain metals; calcium chloride and aluminum chloride, (0.01 mg /100 ml medium) for metabolic regulation of anamorph and teleomorph stages formation. The percentage of teleomorph and anamorph forms, as represented by the presence of cleistothecia and conidial heads, respectively was calculated by using a hemacytometer.

Secondary metabolites detection

Secondary metabolites were determined by the method described by Paterson & Bridge (1994) as follows the fungal mat of Eurotium repens was harvested and the fungal growth medium was filtered and extracted with equal volume of chloroform : methanol (2:1, v/v), left to evaporate till dryness and then dissolved in 1 ml of extraction solvent.

The extraction concentrates were spotted on a pre-coated thin layer chromatography (TLC) plate (20 × 20 cm aluminum sheet silica gel 60, layer thickness 0.2 mm) along with griseofulvin as a standard reference. The metabolites were eluted using toluene: ethyl acetate: 90% formic acid (5:4: 1, v/v/v). The developed secondary metabolites spots were visualized for their colour and Rf under white, UV (365 nm), UV (254 nm) and back under UV (365 nm) light, respectively. The plate was then sprayed with 0.5 % (w/v) ρ - anisaldehyde in methanol: acetic acid: concentrated sulphuric acid (17:2:1, v/v/v) and visualized under white light. The plat was heated for 8 min at 105°C and reexamined under white, UV (365 nm) and UV (254 nm) light, respectively.
Amino acids analysis

Cell free extracts was prepared by grinding the fresh fungal mycelium (5 gm) in a sterile mortar with 70% ethanol (v/v). The slurry was centrifuged at 600 rpm. for 10 min, and the supernatant was concentrated using a vacuum desiccators. The concentrated cell free extract was analyzed for amino acids qualitatively and quantitatively with a fully automated Amino Acid analyzer: Model LC 3000 (Eppendorf Biotronik, Germany) at the Regional Center for Mycology and Biotechnology Al-Azhar University.

Metals analysis

Dry fungal mycelium (0.5 gm) was ground and analyzed for metals with a Fei QUANTA 200 Environmental scanning electron microscope with Edex Unit Micro-analysis.

Antimicrobial activity

The antimicrobial activities of extra- and intracellular secondary metabolites were determined by the filter paper disc method (Nester et al., 1983). The filter paper discs, 6 mm in diameter were separately soaked in the extracts and transferred onto the surface of the growth medium seeded with the test organism. After the incubation period, the diameter of the inhibited growth area around the disc (s) was measured.

Results

As showin in Table 1, growth of Eurotium repens increased with increasing sucrose concentration up to 40% reflect a decreasing water activity ($a_w$, 0.82), but then decreased slightly, and failed to grow at 80% sucrose concentration ($a_w$ 0.70). The percentage of teleomorph and anamorph stages formation, detected as showin in Fig. 1, decreased and increased respectively, with increasing sucrose concentration up to 50%. At 60 and 70% sucrose concentration, the fungus failed to reproduce sexually (Table 1).

**Secondary metabolites**

The extracellular secondary metabolites produced by teleomorph and anamorph stages of *Eurotium repens* were different except for two metabolites; epoxy succinic acid and 2-pyruvylaminobenzamide, which produced by the two stages (Table 4). The number of extracellular secondary metabolites produced by teleomorph stage was more than that produced by anamorph stage.

Amino acids

The free amino acids in teleomorph and anamorph stages were varied (Table 5b). Although, the level of all detected free amino acids except glycine was higher in teleomorph than anamorph stage. Alanine and the secondary amino acid α-amino adipic acid were detected only in the teleomorph stage. The
concentration of glutamic acid, alanine, phosphoethanol amine and aspartic acid were considerable higher in teleomorph stage (253.93, 61.88, 61.79 and 40.50 μg/ml, respectively) than other detected amino acids in the same stage. On the other hand, glutamic acid and glycine concentrations (82.79 and 31.97 μg/ml, respectively) were higher than other detected amino acids in anamorph stage.

Metals analysis
There was considerable variation among the teleomorph and anamorph stages in their elemental analysis (Table 6). Most of the detected elements in anamorph stage were present in higher concentration than teleomorph stage except for potassium. Silicon and copper were not detected in teleomorph stage. On the other hand, iron and calcium were not detected in anamorph stage.

Egypt. J. Microbiol. 46 (2011)
Regulation of reproduction by amino acids and metals

Alanine and arginine unlike aspartic acid, glutamic acid and glycine, exhibited stimulatory effect on growth of *Eurotium repens* at low sucrose concentration (2 % w/v), while glycine and arginine exhibited stimulatory effect on growth and teleomorph stage formation at high sucrose concentrations (Table 7). At high sucrose concentration (70 % w/v), the fungus failed to grow on medium amended with alanine and aluminum chloride.

Discussion

In this study the high sucrose concentration 80% (w/v), (a_w 0.70) inhibit the growth of Eurotium repens. Pitt (1975) showed that the lower a_w limit for growth of Eurotium species is approximately 0.70. Fungi reproduce asexually under favorable condition and sexually under stress condition (Griffin, 1994). However Eurotium repens did not reproduce sexually under stress of low water activity 0.75 and 0.72 adjusted by sucrose concentration 60% (w/v) and 70% (w/v), respectively. Recently, Bluhm et al. (2005) found that the conidial heads of Eurotium rubrum were visible after 6 days at 0.98 a_w. Cleistothecia were produced only at 0.98 a_w, however mature ascospores were not detected until 10 days.

From the current study there is indirect relationship between the low a_w and reproduction in Eurotium repens where at low a_w certain amino acids were produced while others not produced. Generally the free amino acids are known to play an important role in the regulation of synthesis of some enzymes, on secondary metabolites production and osmoregulation. The unusual amino acid \( \varepsilon \)-amino adipic acid and alanine were not detected when the Eurotium repens reproduce asexually (anamorph). On the other hand, glycine was only detected in higher concentration in teleomorph than in anamorph. These amino acids may be involved in the regulation of Eurotium repens reproduction. Mc Alpin & Wicklow (2005) stated that high nitrate (0.3% - 0.6% NaNO_3) and high sucrose (10 – 20 %) concentrations were optimal for stromata development. No stromata were produced by Petromyces alliaceus (Anamorph Aspergillus alliaceus) on media in which cystine or ammonium sulphate represented the only source of nitrogen, while the percentage of stromata containing ascocarps was the greatest with ammonium tartrate, glutamic acid, glycine or serine substituted for NaNO_3.

There is a direct relationship between the osmotic stress and polyols, phospholipids and lipid composition in filamentous fungi (Hefnawy, 1993). The growth of Eurotium repens at low water activity (high osmotic stress) may induce synthesis of compounds which may then regulate their reproduction. This information is consistent with previous studies, where fatty acids or related lipids (Nukina et al., 1981 and Goodrich-Tananrikulu et al., 1998) and polyols (Feofilova et al., 2000) affected sexual development in filamentous fungi.

The secondary metabolites detected in teleomorph and anamorph stages of Eurotium repens were generally different; this may be due to differentiation or may be related to other physiological changes. Many previous studies revealed that the production of fungal secondary metabolites is associated with differentiation (sexual and asexual development) and environmental stress (Cotty et al., 1994; Trail et al., 1995; Adams & Yu, 1998; Pena et al., 1998; Chang et al., 2001 and Michael et al., 2001).

Egypt. J. Microbiol. 46 (2011)
From the elemental analysis, calcium was detected only in teleomorph stage, and therefore, when added to the growth medium it stimulates the sexual reproduction at 60% (w/v) sucrose concentration in Eurotium repens. Changes in microcellular Ca$^{2+}$ concentration are known to play an important role in the regulation of all physiological processes occurring in the cell such as growth, division, secretion and development of microbial resting forms (Jackson & Heath, 1993 and Berridge et al., 2000). On the other hand, aluminum suppresses the growth and sexual reproduction in the Eurotium repens, the reduction of spore germination by aluminum was documented by Dursun et al. (2002).

تنظيم التكاثر والنواتج الأيضية الثانوية لفطرة أروشيم ريبنس
محمود عبد المنجى
معهد الهندسة الوراثية والتكنولوجيا الحيوية - جامعة المنوفية - مدينة السادات - مصر.

تم عزل فطر وتعريفه على أنه فطر أروشيم ريبنس وتم نموه على بيئة مزودة
بتركيزات مختلفة من السكرورز فوجد أنه يتكاثر جنسيًا حتى تركيز 50٪ (وزن / حجم) بينما عند التركيز العالي 60٪ (وزن / حجم) يتكاثر لاجنسياً فقط.

وبتحليل الأحماض الأمينية في الطور الكامل والغير كامل وجد أن
الأحماض الأمينية موجودة بتركيزات عالية في الطور الكامل بالمقارنة بالطور
الغير كامل ما عدا الحمض الأميني جليسين بالإضافة إلى وجود حمض ألفا أمين
أديبك والألين في الطور الكامل فقط. ووجد أن نواتج التمثيل الغذائي الثانوية
المنتجة بالغطر في الطور الكامل والغير كامل كانت متنوعة ومختلفة عند إضافة
بعض الأحماض الأمينية على الوسط الغذائي. وقد كان لهم دوراً مهماً
لاستثنا تكوين الطور الكامل عند التركيز العالي 60٪ (وزن / حجم).
